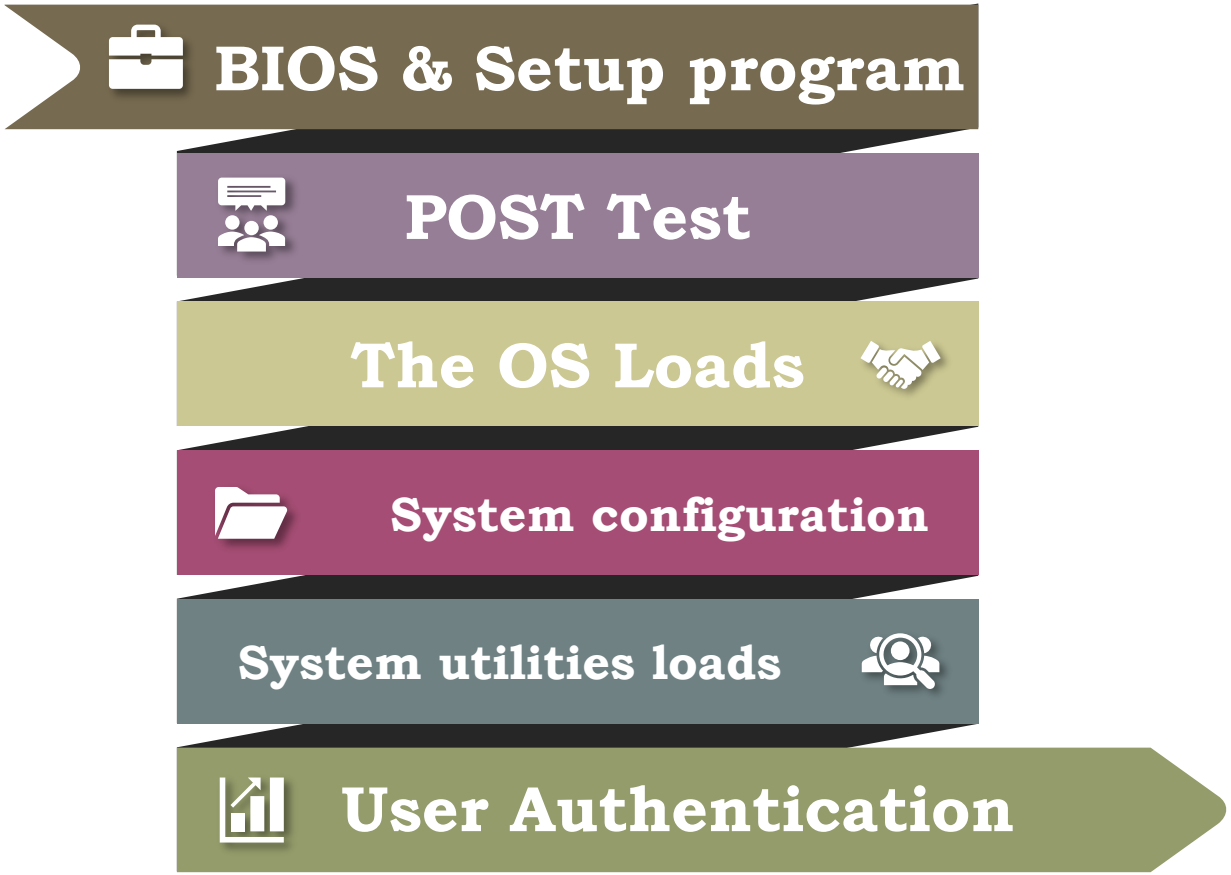
Windows Boot Process

Ways to boot the Windows OS

- **Cold boot**
  - When a computer starts for the 1st time, after power on button is pressed.
- **Hard/Warm boot**
  - Computer restarts while powered on during the hard boot.
  - This is useful while installing or uninstalling the software or updating the machine.

Windows Boot Process



Windows Boot Process (Step 1)

BIOS/EFI

- **BIOS** = Basic Input Output System
  - perform a test POST test
  - Power On Self Test = checking of hardware devices
- **EFI** = Extensible Firmware Interface
  - UEFI = Unified Extensible Firmware Interface
  - its a software between OS & platform firmware (hardware)

Windows Boot Process (Step 2)

MBR

- Master Boot Record
- It contains the address of operating system
- The size of MBR is “512 bytes”.
- The MBR is limited to handling disk sizes up to 2 terabytes (TB).

Windows Boot Process (Step 3)

Volume Boot Sector

- Its a boot sector (by IBM), that contains necessary code to start the boot process.
- The Volume Boot Sector is the first sector of a partitioned storage device that contains code and data necessary to start the boot process for an operating system installed on that volume.

Windows Boot Process (Step 4)

bootmgr.exe

- It accesses the boot configuration data stored & uses the information to load the operating system and calls "winload.exe" or "winresume.exe"
  - **winload.exe**
    - This loads the necessary device drivers & the core part of the OS i.e, kernel (**ntoskrnl.exe**)
  - **winresume.exe**
    - its an OS file that resumes from hibernate boot mode.

Windows Boot Process (Step 5)

ntoskrnl.exe

- The kernel file getting called by bootmgr.exe.
- Full form is “Windows **NT o**perating **s**ystem **kernel exe**cutable”.
- ntoskrnl.exe is the kernel of the Windows operating system, which acts as the core part of the OS, managing interactions between hardware and software.
- It handles memory allocation and deallocation, ensuring that applications have access to the necessary memory resources.
- It manages running processes, ensuring they operate correctly and efficiently.

Windows Boot Process (Step 6)

HAL.DLL

- *Hardware Abstraction Layer. Dynamic Link Library*
- It is a crucial component of windows OS as it acts as a bridge between hardware & software to communicate efficiently.
- This means that the operating system can interact with hardware devices in a consistent manner, without needing to know the specifics of each device.
- By abstracting hardware details, hal.dll helps ensure system stability and compatibility across different hardware configurations.
- It optimizes hardware performance by managing low-level functions and ensuring efficient use of system resources.

Windows Boot Process (Step 7)

SMSS.exe - Session **M**anager **S**ub-**S**ystem

- Its the 1st user mode process started by kernel.
- Once started, it creates additional paging files, env variables located at registry.
- This manager is responsible for starting the kernel and user mode of Win32 system.
- Including win32k.sys, winsrv.dll & csrss.exe (user mode)
- It is also responsible for doing any operations that are requested to be done at the start of the session. Like "autochk" & "convert".
- This manager also started the registry keys.
- After windows vista, SMSS creates a temporary instance of itself that launches the windows startup application (wininit.exe) and a second client/server runtime subsystem (csrss.exe) for dedicated session to start system process
- From here, the windows startup application starts the service control manager (services.exe)

Windows Boot Process (Step 8)

CSRSS.exe

- Client/Server Runtime Sub-System
- Primarily, it will load the process & thread mgmt, console windows handling, side by side assembly & shutdown process.
- This is a very CRUICIAL process, as killing one process can lead to crash of the OS giving the BSOD (Blue Screen of Death).

Windows Hyper-V

- Windows Hyper-V is a virtualization technology developed by Microsoft that allows users to create and manage virtual machines on a single physical machine.
- Key Features of Windows Hyper-V:
  - Virtual Machines
  - Isolation Environments
  - Resource Allocation
  - Virtual Switches
  - Supports Virtual Desktop Infrastructure (VDI)
